Regular Expressions

Data Wrangling, Session 5

Kieran Healy
Code Horizons

October 2, 2024

A brief introduction to regular expressions

Load the packages, as always

```
library(here)      # manage file paths
library(socviz)    # data and some useful functions
```

```
library(tidyverse) # your friend and mine
library(gapminder) # gapminder data
library(stringr)
```

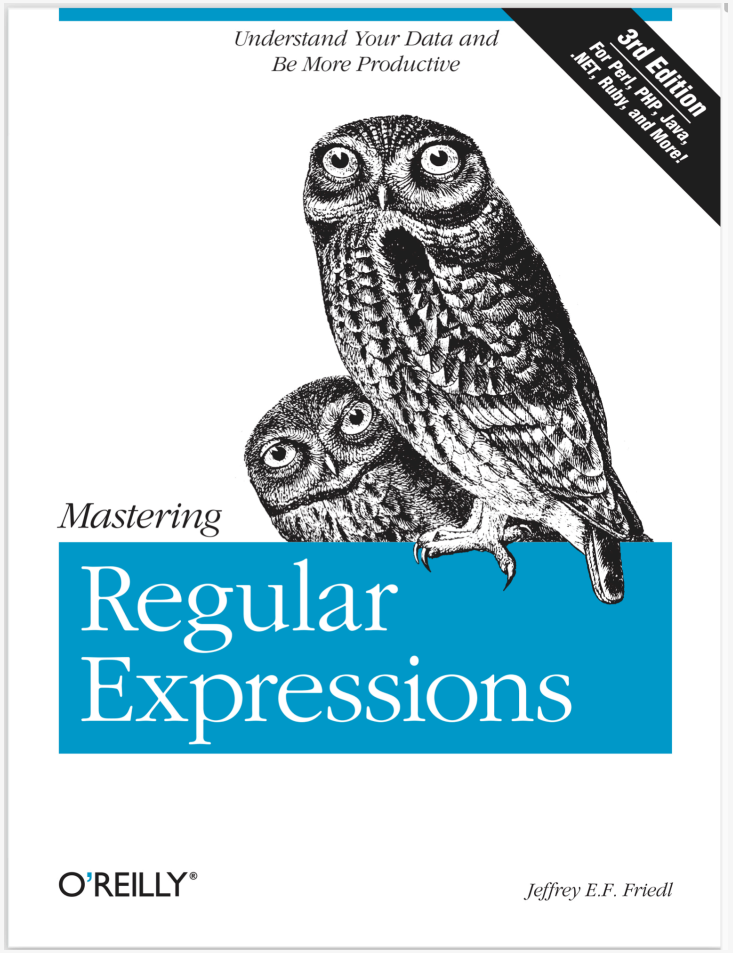
Regular Expressions

Or, waiter, there appears to be a language inside my language

stringr is your gateway to regexps

```
library(stringr) # It's loaded by default with library(tidyverse)
```

regexps are their own whole world



This book is a thing of beauty.

Searching for patterns

A regular expression is a way of searching for a piece of text, or *pattern*, inside some larger body of text, called a *string*.

Searching for patterns

Here I'll follow the exposition in Wickham & Grolemund (2017).

```
x ← c("apple", "banana", "pear")

str_view(x, "an", html=FALSE)
```

```
[2] │ b<an><an>a
```

Searching for patterns

Escaping

Hang on, I see a further problem

We use strings to represent regular expressions. \ is also used as an escape symbol in strings. So to create the regular expression \. we need the string \\.

```
# To create the regular expression, we need \\
dot ← "\\."

# But the expression itself only contains one:
writeLines(dot)
```

```
\.
```

```
# And this tells R to look for an explicit .
str_view(c("abc", "a.c", "bef"), "a\\.c")
```

```
[2] │ <a.c>
```

But … how do you match a literal \?

```
x ← "a\\b"
writeLines(x)
```

```
a\b
```

```
#> a\b

str_view(x, "\\\\") # you need four!
```

```
[1] │ a<\>b
```

But … how do you match a literal \?

This is the price we pay for having to express searches for patterns using a language containing these same characters, which we may also want to search for.

I *promise* this will pay off

Matching start and end

Use ^ to match the start of a string.

```
x ← c("apple", "banana", "pear")
str_view(x, "^a")
```

```
[1] | <a>pple
```

Matching start and end

Use ^ to match the start of a string.

```
x ← c("apple", "banana", "pear")
str_view(x, "^a")
```

```
[1] | <a>pple
```

Use $ to match the end of a string.

```
str_view(x, "a$")
```

```
[2] | banan<a>
```

Matching start and end

To force a regular expression to only match a complete string, anchor it with both ^ and $

```
x ← c("apple pie", "apple", "apple cake")
str_view(x, "apple")
```

```
[1] │ <apple> pie
[2] │ <apple>
[3] │ <apple> cake
```

```
str_view(x, "^apple$")
```

```
[2] │ <apple>
```

Matching character classes

\d matches any digit.

\s matches any whitespace (e.g. space, tab, newline).

abc matches a, b, or c.

^abc matches anything except a, b, or c.

Matching the *special* characters

Look for a literal character that normally has special meaning in a regex:

```
str_view(c("abc", "a.c", "a*c", "a c"), "a[.]c")
```

```
[2] | <a.c>
```

```
str_view(c("abc", "a.c", "a*c", "a c"), ".[*]c")
```

```
[3] | <a*c>
```

This works for most (but not all) regex metacharacters: $. | ? * + ( ) [{. Unfortunately, a few characters have special meaning even inside a character class and must be handled with backslash escapes. These are] \ ^ and -

Alternation

Use parentheses to make the precedence of the ‘or’ operator | clear:

```
str_view(c("groy", "grey", "griy", "gray"), "gr(e|a)y")
```

```
[2] │ <grey>
[4] │ <gray>
```

Repeated patterns

? is 0 or 1

+ is 1 or more

* is 0 or more

```
x ← "1888 is the longest year in Roman numerals: MDCCCLXXXVIII"
str_view(x, "CC?")
```

```
[1] │ 1888 is the longest year in Roman numerals: MD<CC><C>LXXXVIII
```

Repeated patterns

? is 0 or 1

+ is 1 or more

* is 0 or more

```
str_view(x, "CC+")
```

```
[1] │ 1888 is the longest year in Roman numerals: MD<CCC>LXXXVIII
```

Repeated patterns

? is 0 or 1

+ is 1 or more

* is 0 or more

```
x ← "1888 is the longest year in Roman numerals: MDCCCLXXXVIII"
str_view(x, 'C[LX]+')
```

```
[1] │ 1888 is the longest year in Roman numerals: MDCC<CLXXX>VIII
```

Exact numbers of repetitions

{n} is exactly n

{n,} is n or more

{,m} is at most m

{n,m} is between n and m

```
str_view(x, "C{2}")
```

```
[1] │ 1888 is the longest year in Roman numerals: MD<CC>CLXXXVIII
```

Exact numbers of repetitions

{n} is exactly n

{n,} is n or more

{,m} is at most m

{n,m} is between n and m

```
str_view(x, "C{2,}")
```

```
[1] │ 1888 is the longest year in Roman numerals: MD<CCC>LXXXVIII
```

Exact numbers of repetitions

{n} is exactly n

{n,} is n or more

{,m} is at most m

{n,m} is between n and m

```
str_view(x, "C{2,3}")
```

```
[1] │ 1888 is the longest year in Roman numerals: MD<CCC>LXXXVIII
```

Exact numbers of repetitions

{n} is exactly n

{n,} is n or more

{,m} is at most m

{n,m} is between n and m

By default regexps use *greedy* matches. You can make them match the *shortest* string possible by putting a ? after them. **This is often very useful!**

```
str_view(x, 'C{2,3}?')
```

```
[1] │ 1888 is the longest year in Roman numerals: MD<CC>CLXXXVIII
```

Exact numbers of repetitions

{n} is exactly n

{n,} is n or more

{,m} is at most m

{n,m} is between n and m

By default these are *greedy* matches. You can make them "lazy", matching the shortest string possible by putting a ? after them. **This is often very useful!**

```
str_view(x, 'C[LX]+?')
```

```
[1] │ 1888 is the longest year in Roman numerals: MDCC<CL>XXXVIII
```

And finally ... backreferences

```
fruit # built into stringr
```

```
 [1] "apple"            "apricot"          "avocado"
 [4] "banana"           "bell pepper"      "bilberry"
 [7] "blackberry"       "blackcurrant"     "blood orange"
[10] "blueberry"        "boysenberry"      "breadfruit"
[13] "canary melon"     "cantaloupe"       "cherimoya"
[16] "cherry"           "chili pepper"     "clementine"
[19] "cloudberry"       "coconut"          "cranberry"
[22] "cucumber"         "currant"          "damson"
[25] "date"             "dragonfruit"      "durian"
[28] "eggplant"         "elderberry"       "feijoa"
[31] "fig"              "goji berry"       "gooseberry"
[34] "grape"            "grapefruit"       "guava"
[37] "honeydew"         "huckleberry"      "jackfruit"
[40] "jambul"           "jujube"           "kiwi fruit"
[43] "kumquat"          "lemon"            "lime"
[46] "loquat"           "lychee"           "mandarine"
[49] "mango"            "mulberry"         "nectarine"
[52] "nut"              "olive"            "orange"
[55] "pamelo"           "papaya"           "passionfruit"
```

Grouping and backreferences

Find all fruits that have a repeated pair of letters:

```
str_view(fruit, "(..)\\1", match = TRUE)
```

```
 [4] │ b<anan>a
[20] │ <coco>nut
[22] │ <cucu>mber
[41] │ <juju>be
[56] │ <papa>ya
[73] │ s<alal> berry
```

Grouping and backreferences

Backreferences and grouping will be very useful for string *replacements*.

OK that was a lot

Learning and testing regexps

Practice with a tester like https://regexr.com or https://regex101.com

Or an app like Patterns

The regex engine or “flavor” used by `stringr` is Perl- or PCRE2-like.

Regexps in practice

Example: Politics and Placenames

```
library(ukelection2019)
```

Example: Politics and Placenames

```
library(ukelection2019)

ukvote2019
