                                                  38321 Deaths
# i 361 more rows
```

Here the count measure is *cumulative* deaths. What if we want to recover the daily count for all the states in the data?

### An application

dplyr has **lead()** and **lag()** functions. These allow you to access the previous and next values in a vector. You can calculate offsets this way.

# An application

We can write the expression directly:

```
covus >
  select(-data_quality_grade) >
  filter(measure = "death") ▷
  group_by(state) ▷
  arrange(date) ▷
  mutate(deaths_daily = count - lag(count, order_by = date)) >
  arrange(state, desc(date)) ▷
  filter(state %in% "NY")
# A tibble: 371 × 7
# Groups: state [1]
   date state fips measure count measure_label deaths daily
          <chr> <chr> <chr>
                                 <dbl> <chr>
   <date>
                                                            <dbl>
 1 2021-03-07 NY
                         death
                                39029 Deaths
                                                               59

                         death
                                 38321 Deaths
                                                               94
# i 361 more rows
```

#### Writing our own functions

We write functions using the special function() function.\*

```
my_fun \leftarrow function(x) {
  x + 1
my_fun # we've created the function; it's just an object
function(x) {
  x + 1
my_fun(x = 1) # But we can supply it with an input!
[1] 2
my_fun(10)
[1] 11
```

\*Nerds love this sort of stuff.

#### Writing our own functions

We write our function. It's just the expression we originally wrote, wrapped up.

```
get_daily_count ← function(count, date){
  count - lag(count, order_by = date)
}
```

This function has no generality, error-handling, or anything else. It's a once-off.

#### Writing our own functions

Now we can use it like any other:

```
covus >
  filter(measure = "death") ▷
  select(-data quality grade) ▷
  group_by(state) ▷
  arrange(date) ▷
  mutate(deaths_daily = get_daily_count(count, date)) >
  arrange(state, desc(date)) ▷
  filter(state %in% "NY")
# A tibble: 371 \times 7
# Groups: state [1]
  date state fips measure count measure_label deaths daily
  <date> <chr> <chr> <chr> <dbl> <chr>
                                                           <dbl>

# The slider package

# Tidy moving averages with slider

dplyr's window functions don't include moving averages.

There are several options, notably RcppRoll

We'll use the slider package.

# install.packages("slider")
library(slider)

# Tidy moving averages with slider

```
covus >
  filter(measure = "death") ▷
  select(-data_quality_grade) ▷
  group_by(state) ▷

# Tidy moving averages with slider

Notice the Tidyverse-style na\_rm argument rather than the usual base na.rm

The package provides a lot of different functions, from general-purpose <code>slide\_max()</code>, <code>slide\_min()</code> to more specialized sliding functions. In particular note e.g. <code>slide\_index\_mean()</code> that addresses some subtleties in averaging over dates with gaps.

# Recap and Looking Ahead

### Recap and Looking Ahead

Coding as gardening
Working in RStudio with RMarkdown
documents

#### Core dplyr verbs

```
Subset your table: filter() rows, select() columns
Logically group_by() one or more columns
Add columns with mutate()
Summarize (by group, or the whole table) with summarize()
```

#### Expand your dplyr actions

```
Count up rows with n(), tally() or count()
Calculate quantities with sum(), mean(), min(), etc
Subset rows with logical expressions or slice functions
Conditionally select columns by name directly, with %in% or %nin%, or
with tidy selectors like starts_with(), ends_with(), contains()
Conditionally select columns by type with where () and some criterion,
e.g. where(is.numeric)
Conditionally select and then act on columns with
across(where(<condition>), <action>)
```

### Expand your dplyr actions

```
Tidy up columns with relocate() and rename()
Tidy up rows with arrange()
```

So far we have been writing, e.g.,

```
gss_sm ▷
  group_by(bigregion, religion) ▷
  summarize(total = n())
# A tibble: 24 × 3
# Groups: bigregion [4]
  bigregion religion
                     total
  <fct> <fct>
                       <int>
1 Northeast Protestant
                        158
2 Northeast Catholic
                         162
3 Northeast Jewish
                          27
 4 Northeast None
                         112
 5 Northeast Other
                          28
 6 Northeast <NA>
7 Midwest Protestant
                         325
8 Midwest Catholic
                         172
9 Midwest Jewish
                           3
10 Midwest None
                         157
# i 14 more rows
```

#### Or

```
gss_sm ▷
  group_by(bigregion, religion) ▷
  tally()
# A tibble: 24 \times 3
# Groups: bigregion [4]
   bigregion religion
                           n
   <fct> <fct>
                       <int>
 1 Northeast Protestant
                         158
 2 Northeast Catholic
                         162
 3 Northeast Jewish
                          27
 4 Northeast None
                         112
 5 Northeast Other
                          28
 6 Northeast <NA>
 7 Midwest Protestant
                          325
 8 Midwest Catholic
                         172
 9 Midwest Jewish
                           3
10 Midwest None
                         157
# i 14 more rows
```

#### Or

```
gss_sm >
  count(bigregion, religion)
# A tibble: 24 \times 3
  bigregion religion
                           n
  <fct> <fct>
                       <int>
 1 Northeast Protestant
                         158
 2 Northeast Catholic
                         162
3 Northeast Jewish
                          27
 4 Northeast None
                         112
 5 Northeast Other
                           28
 6 Northeast <NA>
7 Midwest Protestant
                          325
8 Midwest Catholic
                         172
9 Midwest Jewish
10 Midwest None
                         157
# i 14 more rows
```

With this last one the final result is *ungrouped*, no matter how many levels of grouping there are going in.

#### But we can also write this:

```
gss_sm ▷
  summarize(total = n(), .by = c(bigregion, religion))
# A tibble: 24 \times 3
   bigregion religion
                        total
   <fct> <fct>
                        <int>
1 Northeast None
                          112
 2 Northeast Catholic
                          162
                          158
3 Northeast Protestant
 4 Northeast Other
                            28
 5 Northeast Jewish
                            27
 6 West
            Jewish
                           10
7 West None
8 West Other
9 West Protestant
                           180
                           48
                           238
10 West Catholic
                          155
# i 14 more rows
```

By default the result is an *ungrouped* tibble, whereas with group\_by() ... summarize() the result would still be grouped by bigregion at the end. To prevent unexpected results, you can't use .by on tibble that's already grouped.

## Data as implicitly first

#### This code:

```
gss_sm ▷
  summarize(total = n(), .by = c(bigregion, religion))
# A tibble: 24 × 3
  bigregion religion total
  <fct> <fct>
                      <int>
1 Northeast None
                      112
2 Northeast Catholic
                       162
3 Northeast Protestant
                       158
4 Northeast Other
                        28
5 Northeast Jewish
                        27
6 West Jewish
                        10
7 West None
                       180
8 West Other
                       48
9 West Protestant
                       238
10 West
       Catholic
                       155
# i 14 more rows
```

### Data as implicitly first

... is equivalent to this:

```
summarize(gss_sm, total = n(), .by = c(bigregion, religion))
# A tibble: 24 \times 3
   bigregion religion total
   <fct> <fct>
                          <int>
 1 Northeast None
                        112
 2 Northeast Catholic
                           162
 3 Northeast Protestant
                           158
 4 Northeast Other
                            28
 5 Northeast Jewish
 6 West Jewish
                            10
7 West None
8 West Other
9 West Protestant
10 West Catholic
                            180
                            48
                            238
                            155
# i 14 more rows
```

This is true of Tidyverse pipelines in general. Let's look at the help for summarize() to see why.

# Two dplyr gotchas

Let's say you are working with proportions ...

And you want to focus on cases where prop1 *plus* prop2 is greater than 0.3:

The row with id A shouldn't have been included there.

This is not dplyr's fault. It's our floating point friend again.

```
df >
  filter(prop1 + prop2 = 0.3)

# A tibble: 0 × 3
# i 3 variables: id <chr>>, prop1 <dbl>>, prop2 <dbl>>
```

The row with id **A** *should* have been included here!

This won't give the right behavior either:

```
df >
  mutate(prop3 = prop1 + prop2) >
  filter(prop3 = 0.3)

# A tibble: 0 × 4
# i 4 variables: id <chr>>, prop1 <dbl>>, prop2 <dbl>>, prop3 <dbl>>
```

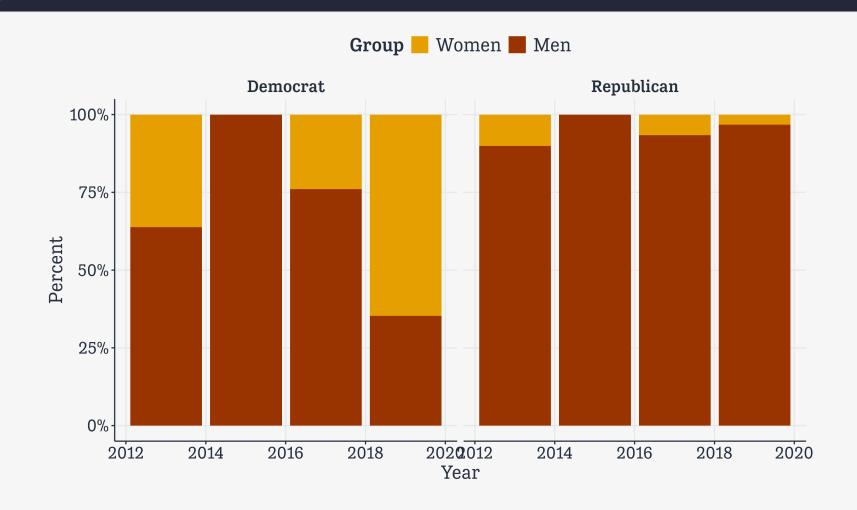

#### So, beware.

#### Better:

```
df ← read_csv(here("data", "first_terms.csv"))
df
# A tibble: 280 × 4
     pid start_year party
                              sex
   <dbl> <date>

                              33 0.647
```

You can make dplyr keep empty factor levels though:

```
df ⊳
  mutate(across(where(is.character), as_factor)) >
  group_by(start_year, party, sex, .drop = FALSE) >
  summarize(N = n()) \triangleright
  mutate(freq = N / sum(N))
# A tibble: 16 \times 5
# Groups: start_year, party [8]
  start_year party sex
                                N freq
             <fct> <fct> <int> <dbl>
  <date>
1 2013-01-03 Republican M
                         71 0.899
2 2013-01-03 Republican F 8 0.101
                          37 0.638
3 2013-01-03 Democrat M
                            21 0.362
4 2013-01-03 Democrat F
5 2015-01-03 Republican M
                             5 1
6 2015-01-03 Republican F
                                0 0
7 2015-01-03 Democrat
                                1 1
8 2015-01-03 Democrat
                                0 0
9 2017-01-03 Republican M
                                28 0.933
10 2017-01-03 Republican F
                              2 0.0667
11 2017-01-03 Democrat M
                               19 0.76
12 2017-01-03 Democrat F
                              6 0.24
13 2019-01-03 Republican M
                              30 0.968
14 2019-01-03 Republican F
                              1 0.0323
15 2019-01-03 Democrat M
                                18 0.353
```

Maybe you don't want to deal with factors.

```
df_c 		 df 		 group_by(start_year, party, sex) 		 summarize(N = n()) 		 mutate(freq = N / sum(N)) 		 ungroup() 		 complete(start_year, party, sex, fill = list(N = 0, freq = 0))
```

#### df\_c

```
# A tibble: 16 × 5
  start year party
                        sex
                                  N freq
                   <chr> <int> <dbl>
  <date>
             <chr>
                                 21 0.362
