                                                  38321 Deaths
# i 361 more rows
```

Here the count measure is *cumulative* deaths. What if we want to recover the daily count for all the states in the data?

An application

dplyr has **lead()** and **lag()** functions. These allow you to access the previous and next values in a vector. You can calculate offsets this way.

An application

We can write the expression directly:

```
covus >
  select(-data_quality_grade) ▷
  filter(measure = "death") ▷
  group_by(state) ▷
  arrange(date) ▷
  mutate(deaths_daily = count - lag(count, order_by = date)) >
  arrange(state, desc(date)) ▷
  filter(state %in% "NY")
# A tibble: 371 × 7
# Groups: state [1]
  date
              state fips measure count measure_label deaths_daily
              <chr> <chr> <chr>
                                 <dbl> <chr>
   <date>
                                                             <dbl>
1 2021-03-07 NY
                                 39029 Deaths
                          death
                                                                59
 2 2021-03-06 NY
                          death
                                 38970 Deaths
                                                               79
                                 38891 Deaths
                                                                95

# i 361 more rows
```

Writing our own functions

We write functions using the special function() function.*

```
my_fun \leftarrow function(x) {
my_fun # we've created the function; it's just an object
function(x) {
  x + 1
my_fun(x = 1) # But we can supply it with an input!
[1] 2
my_fun(10)
[1] 11
```

^{*}Nerds love this sort of stuff.

Writing our own functions

We write our function. It's just the expression we originally wrote, wrapped up.

```
get_daily_count ← function(count, date){
  count - lag(count, order_by = date)
}
```

This function has no generality, error-handling, or anything else. It's a once-off.

Writing our own functions

Now we can use it like any other:

```
covus >
  filter(measure = "death") ▷
  select(-data_quality_grade) ▷
  group_by(state) ▷
  arrange(date) ▷
  mutate(deaths_daily = get_daily_count(count, date)) >
  arrange(state, desc(date)) ▷
  filter(state %in% "NY")
# A tibble: 371 × 7

Not super-useful quite yet, but if our task had more steps ...

The slider package

Tidy moving averages with slider

dplyr's window functions don't include moving averages.

There are several options, notably RcppRoll

We'll use the slider package.

install.packages("slider")
library(slider)

Tidy moving averages with slider

```
covus ▷
  filter(measure = "death") ▷
  select(-data_quality_grade) ▷
  group_by(state) ▷
  arrange(date) ▷
  mutate(
    deaths_daily = get_daily_count(count, date),
    deaths7 = slide_mean(deaths_daily,
                         before = 7,
                         na_rm = TRUE)) ▷
  arrange(state, desc(date)) ▷
  filter(state %in% "NY")

Tidy moving averages with slider

```
deaths7 = slide_mean(deaths_daily,

before = 7,

na_rm = TRUE)<u>)</u> >
```

Notice the Tidyverse-style na_rm argument rather than the usual base na.rm

The package provides a lot of different functions, from general-purpose <code>slide_max()</code>, <code>slide_min()</code> to more specialized sliding functions. In particular note e.g. <code>slide_index_mean()</code> that addresses some subtleties in averaging over dates with gaps.

Move columns with relocate()

Recap and Looking Ahead

Recap and Looking Ahead

Coding as gardening

Working in RStudio with RMarkdown documents

Core dplyr verbs

```
Subset your table: filter() rows, select() columns
Logically group_by() one or more columns
Add columns with mutate()
Summarize (by group, or the whole table) with summarize()
```

Expand your dplyr actions

```
Count up rows with n(), tally() or count()
Calculate quantities with sum(), mean(), min(), etc
Subset rows with logical expressions or slice functions
Conditionally select columns by name directly, with %in% or %nin%, or with
tidy selectors like starts_with(), ends_with(), contains()
Conditionally select columns by type with where () and some criterion,
e.g. where(is.numeric)
Conditionally select and then act on columns with
across(where(<condition>), <action>)
```

Expand your dplyr actions

```
Tidy up columns with relocate() and rename()
Tidy up rows with arrange()
```

So far we have been writing, e.g.,

```
gss_sm ▷
  group_by(bigregion, religion) ▷
  summarize(total = n())
# A tibble: 24 × 3
# Groups: bigregion [4]
  bigregion religion
                      total
            <fct>
  <fct>
                       <int>
 1 Northeast Protestant
                        158
 2 Northeast Catholic
                         162
 3 Northeast Jewish
                          27
 4 Northeast None
                         112
 5 Northeast Other
                          28
 6 Northeast <NA>
 7 Midwest Protestant
                         325
 8 Midwest Catholic
                         172
 9 Midwest Jewish
10 Midwest None
                         157
# i 14 more rows
```

Or

```
gss_sm ▷
  group_by(bigregion, religion) ▷
  tally()
# A tibble: 24 × 3
# Groups: bigregion [4]
  bigregion religion
                           n
  <fct>
            <fct>
                       <int>
 1 Northeast Protestant
                        158
 2 Northeast Catholic
                         162
 3 Northeast Jewish
                          27
 4 Northeast None
                         112
 5 Northeast Other
                          28
 6 Northeast <NA>
 7 Midwest Protestant
                         325
 8 Midwest Catholic
                         172
 9 Midwest Jewish
10 Midwest None
                         157
# i 14 more rows
```

Or

```
gss_sm ▷
  count(bigregion, religion)
# A tibble: 24 × 3
  bigregion religion
                           n
  <fct> <fct>
                       <int>
 1 Northeast Protestant
                        158
 2 Northeast Catholic
                         162
                          27
 3 Northeast Jewish
 4 Northeast None
                         112
 5 Northeast Other
 6 Northeast <NA>
 7 Midwest Protestant
                         325
 8 Midwest Catholic
                         172
 9 Midwest Jewish
10 Midwest None
                         157
# i 14 more rows
```

With this last one the final result is *ungrouped*, no matter how many levels of grouping there are going in.

But we can also write this:

```
gss_sm ▷
  summarize(total = n(), .by = c(bigregion, religion))
# A tibble: 24 × 3
  bigregion religion
                     total
  <fct>
           <fct>
                      <int>
1 Northeast None
                        112
 2 Northeast Catholic
                        162
 3 Northeast Protestant
                        158
4 Northeast Other
                         28
5 Northeast Jewish
                         27
6 West
            Jewish
                         10
                        180
7 West
        None
8 West
        Other
                         48
9 West
        Protestant
                        238
10 West
        Catholic
                        155
# i 14 more rows
```

By default the result is an *ungrouped* tibble, whereas with group_by() ... summarize() the result would still be grouped by bigregion at the end. To prevent unexpected results, you can't use .by on tibble that's already grouped.

Data as implicitly first

This code:

```
gss_sm ▷
  summarize(total = n(), .by = c(bigregion, religion))
# A tibble: 24 × 3
  bigregion religion
                     total
  <fct> <fct>
                      <int>
 1 Northeast None
                        112
 2 Northeast Catholic
                        162
 3 Northeast Protestant
                        158
 4 Northeast Other
                         28
 5 Northeast Jewish
                         27
 6 West
            Jewish
                         10
 7 West
         None
                        180
 8 West
        Other
                         48
 9 West
        Protestant
                        238
10 West
        Catholic
                        155
# i 14 more rows
```

Data as implicitly first

... is equivalent to this:

```
summarize(gss_sm, total = n(), .by = c(bigregion, religion))
# A tibble: 24 × 3
  bigregion religion
                      total
  <fct>
            <fct>
                       <int>
1 Northeast None
                        112
 2 Northeast Catholic
                        162
 3 Northeast Protestant
                        158
4 Northeast Other
                          28
 5 Northeast Jewish
                          27
6 West
            Jewish
                         10
7 West
           None
                         180
        Other
8 West
                         48
9 West
        Protestant
                         238
        Catholic
10 West
                        155
# i 14 more rows
```

This is true of Tidyverse pipelines in general. Let's look at the help for summarize() to see why.

Two dplyr gotchas

Let's say you are working with proportions ...

And you want to focus on cases where prop1 plus prop2 is greater than 0.3:

```
df >
  filter(prop1 + prop2 = 0.3)

# A tibble: 0 × 3
# i 3 variables: id <chr>>, prop1 <dbl>>, prop2 <dbl>>
```

The row with id A *should* have been included here!

This won't give the right behavior either:

```
df >
  mutate(prop3 = prop1 + prop2) >
  filter(prop3 = 0.3)

# A tibble: 0 × 4
# i 4 variables: id <chr>, prop1 <dbl>, prop2 <dbl>, prop3 <dbl>
```

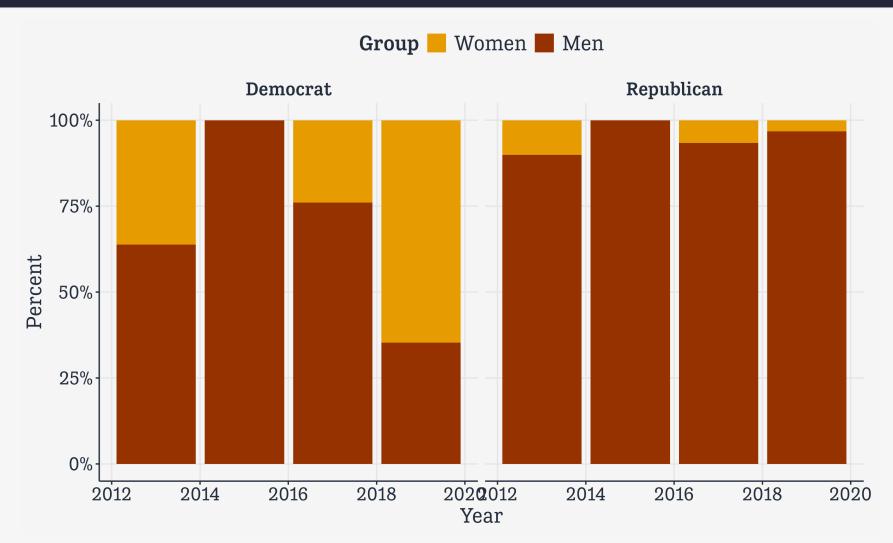

So, beware.

Better:

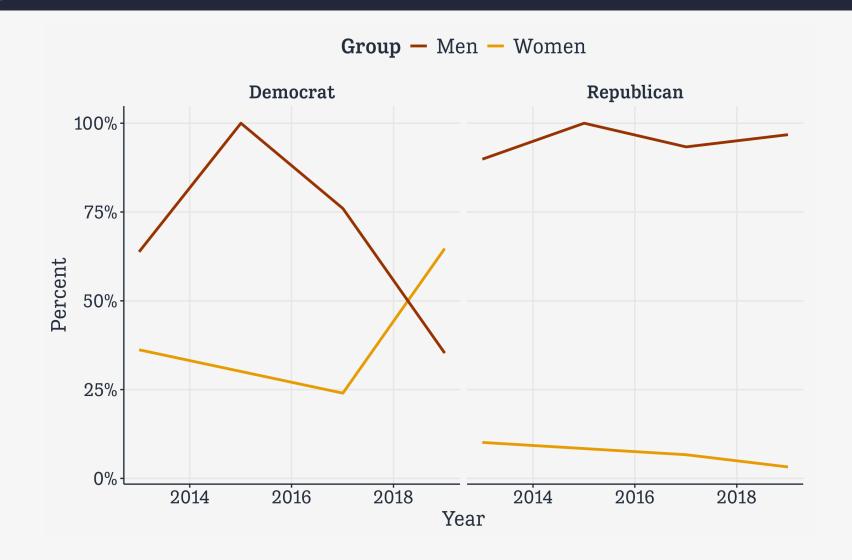

```
df ← read_csv(here("data", "first_terms.csv"))
# A tibble: 280 × 4
    pid start_year party
                             sex
   <dbl> <date>
                  <chr>
                             <chr>

p_col

p_line

Factors are for categorical variables and are stored differently from characters. This can matter when modeling, and also now.

```
df f \leftarrow df \triangleright
  mutate(party_f = factor(party))
df_f
# A tibble: 280 × 5
     pid start_year party
                            sex party_f
   <dbl> <date>
                   <chr>
                            <chr> <fct>
  3160 2013-01-03 Republican M
                                     Republican
 2 3161 2013-01-03 Democrat F
                                    Democrat
  3162 2013-01-03 Democrat M
                                    Democrat
 4 3163 2013-01-03 Republican M
                                    Republican
 5 3164 2013-01-03 Democrat M
                                    Democrat
 6 3165 2013-01-03 Republican M
                                    Republican
 7 3166 2013-01-03 Republican M
                                    Republican
 8 3167 2013-01-03 Democrat F
                                    Democrat
 9 3168 2013-01-03 Republican M
                                    Republican
10 3169 2013-01-03 Democrat M
                                    Democrat
# i 270 more rows
```

Factors are integer values with named labels, or *levels*:

```
typeof(df_f$party_f)

[1] "integer"

levels(df_f$party_f)

[1] "Democrat" "Republican"
```

By default, unused levels won't display:

```
df_f \leftarrow df \triangleright
  mutate(party_f = factor(party,
                            levels = c("Democrat",
                                        "Republican",
                                        "Libertarian")))
df_f ▷
  group_by(party_f) ▷
  tally()
# A tibble: 2 × 2
  party_f
  <fct>
              <int>
1 Democrat
               135
2 Republican
              145
levels(df_f$party_f)
[1] "Democrat"
                   "Republican" "Libertarian"
```

By default, unused levels won't display:

```
df ⊳
  mutate(across(where(is.character), as_factor)) >
  group_by(start_year, party, sex) ▷
  summarize(N = n()) \triangleright
  mutate(freq = N / sum(N))
# A tibble: 14 × 5
# Groups: start_year, party [8]
  start_year party sex
                                N freq
            <fct> <fct> <int> <dbl>
  <date>
1 2013-01-03 Republican M
                               71 0.899
2 2013-01-03 Republican F
                          8 0.101
3 2013-01-03 Democrat M
                               37 0.638
4 2013-01-03 Democrat F
                               21 0.362
5 2015-01-03 Republican M
                           5 1
6 2015-01-03 Democrat M
                                1 1
7 2017-01-03 Republican M
                               28 0.933
8 2017-01-03 Republican F
                           2 0.0667
9 2017-01-03 Democrat M
                               19 0.76
                              6 0.24
10 2017-01-03 Democrat F
11 2019-01-03 Republican M
                               30 0.968
12 2019-01-03 Republican F
                              1 0.0323
13 2019-01-03 Democrat M
                               18 0.353
14 2019-01-03 Democrat F
                               33 0.647
```

You can make dplyr keep empty factor levels though:

```
df ⊳
  mutate(across(where(is.character), as_factor)) >
  group_by(start_year, party, sex, .drop = FALSE) >
  summarize(N = n()) \triangleright
  mutate(freq = N / sum(N))
# A tibble: 16 × 5
# Groups: start_year, party [8]
  start_year party sex
                                 N freq
             <fct> <fct> <fct> <int> <dbl>
  <date>
 1 2013-01-03 Republican M
                                71 0.899
 2 2013-01-03 Republican F 8 0.101
 3 2013-01-03 Democrat M
                                37 0.638
 4 2013-01-03 Democrat F
                                21 0.362
 5 2015-01-03 Republican M
                                5 1
 6 2015-01-03 Republican F
                                 0 0
 7 2015-01-03 Democrat M
                                1 1
                                 0 0
 8 2015-01-03 Democrat F
 9 2017-01-03 Republican M
                                28 0.933
10 2017-01-03 Republican F
                               2 0.0667

```

Maybe you don't want to deal with factors.

```
df_c 	 df 	 group_by(start_year, party, sex) 	 summarize(N = n()) 	 mutate(freq = N / sum(N)) 	 ungroup() 	 ungroup() 	 complete(start_year, party, sex, fill = list(N = 0, freq = 0))
```

df_c

```
